PENETRATION TESTING PROJECT REPORT

HAMDAN KAISER

STUDENT ID: 20030057

YEAR: 2021

## **Abstract**

The main purpose of this project is to conduct a grey-box penetration testing to testing sustainability, analysis and findings of security holes that can be allow someone access to the system with an unauthorised access. This penetration is being done with the purpose of to check how the system could be effected, how risk the system is for the organisation, what and how much data could be stolen from the server and how much the system could be manipulated by the attacker. In order to take further actions against the system, this project consists of several number of penetration testing tasks that triggers few testing on the target machine which is the company's system according to our pre-prepared planning as we discussed on assignment 1. After the testing is being done, we will be preparing our penetration testing report.

After conducting vulnerability analysis, the result that we found scanning on the target shows that some of the open port allows attackers to let into their directories individually by which the information of user credentials can be found. Also, not only the credentials, but also we are able to access into the remote server and their root directories using these credentials as well. Three vulnerabilities were chosen to be exploited using the Kali Linux using VMware, metasploit, OpenVAS, Nessus and other methods as well.

# Security testing of a Linux-based Computer System

## 1.0 Introduction

This penetration testing project is completed based on our penetration testing module, where we learnt security testing, vulnerability analysis, exploitation as well as post exploitation of a system. To take further actions against the security issues of a server, penetration testing against the network provides a layered and structured approach to defend risks that the client might face with an unauthorized access into the server (Shah, 2015). Likewise, this project includes the grey-box penetration testing on the given company's system. The company's system is monitored with a Linux based system where they are already concerned that their security is already been breached. The major purpose of this penetration test is that we are about to figure out the vulnerability of the system, which defines the security holes of the system as well as we will do some malicious attack to make sure how the system can be attacked by a third party attacker. After finding out such issues we are preparing this report to let the company know about their security system.

This penetration testing project was successfully done in response to the client requirements for estimating the system layers using the featured and up to date methods in vulnerability scanning, exploitation and post-exploitation. The first part of the project introduced how we are preparing ourselves to conduct the penetration, in the form of a Standard Operating Procedure (SOP) with the detail procedure of how we will be monitoring this and a Decision Tree. The second part, this report, involves conducting the vulnerability test and analysing the results with exploitation, for the purpose of reporting to the client, including the mitigation methods and the possible risks they need to overcome. This is very important for a company because the economic loss for cyber-attack is increasing over the years. And often, the financial loss arise from theft of information, stolen financial data, and carrying online transaction over the system etc. (nibusinessinfo, 2017) The reputational damage also involves in this massive effect as well. In July 2019, an attacker had gained unauthorised access to the personal data of over 100 million customers in a well-known organisation called Capital One. The suspected attacker, reportedly took benefits from an underdeveloped firewall. From the company later on had the incident to cost it between \$100 million and \$150 million in major for customer notifications, credit monitoring and legal support. (Swinhoe, 2020) A very famous riding organisation UBER had a loss of \$148m (£113m) over a cyber-attack where the attacker stole user's information and exposed 57 million customers' data. (bbc.co.uk, 2017) As a result, The Company paid the hackers \$100,000 to delete the data they grabbed from Uber's servers. (Maru, 2017)

This report illustrates the work that is being done on the following exploits and the risks they might need to recover. This is described in the Attack Narrative section, and then explains the three vulnerabilities from the risks and mitigation point of view. And so on, to explain the whole report.

## 2.0 Attack Narrative

This section of the report describes the following- more detail of target machine, the tools that were used conducting penetration test, the methods those were chosen, paths taken, exploitation and attacking patterns.

### 2.1: Remote System Discovery

For the purpose of this project, we have received an IP address considered as the organisation's systems address where the security has already been breached. To know this, first we did a basic scanning on the IP address where we found how many ports are open. This is important because most of open ports are used for service run into the system, the more open ports are, and the higher the risks are. (David, October 2016) Fig 2.1.1 we can see that the target IP was full of vulnerable.

### 2.2 Scanning and Enumeration

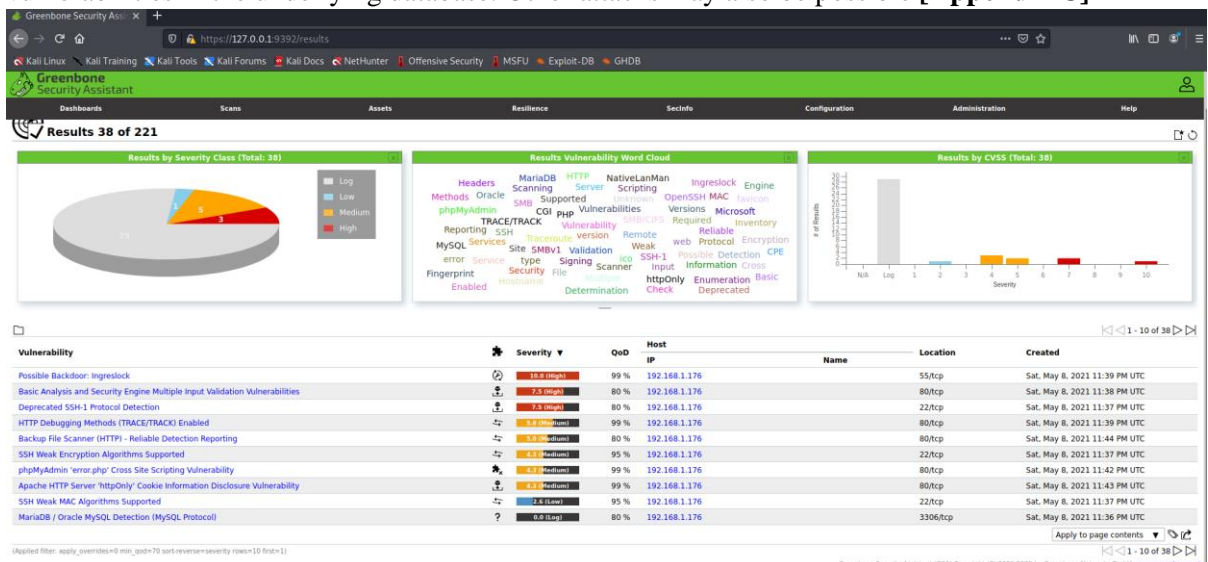

In this section, after receiving IP address, first we used nmap scanning that helps us to scan the particular IP address. By doing so, we found the lists of open ports which is shown in Fig 2.2.1. We found that

there are many open available ports. The open ports allows us to find the vulnerabilities. Among all the open ports, from SSH port we are able to access to the server remotely. In this figure, the lists of identified ports are found, also, we found that the SSH as well as telnet ports are also open. So from this scanning phase it is confirmed that we can have access to the ssh port and telnet port to find the remotely access directories and get into there.

## 2.3 Vulnerability Discovery

This section represents what methods and tools we have used to detect vulnerabilities. This vulnerability discovery allows us to detect and classifies the given system's weaknesses in networks and other side of the data equipment and anticipates the effectiveness of countermeasures. (Porter, 2019) Tools that we have used to scan for vulnerabilities are nmap, zenmap, nessuss, dirb, openVas. These scanning tools we aimed to achieve the threat levels as well as how much trusted the network is. Also it provides us path of the security holes. Some of the vulnerabilities are discussed below-

- OpenVAS Scanning Vulnerability: One major vulnerability we found from OpenVAS is the steal cookie-based authentication credentials, view and execute local files within the context of the webserver, compromise the application, access or modify data, or exploit latent vulnerabilities in the underlying database. Other attacks may also be possible [Appendix C]

- Nmap scanning vulnerability result: by scanning the target IP address with nmap, we found the lists of open ports that are available to breach. Some of the open ports are ssh, http, mysql e.t.c (shown in fig. 2.3.1). To see more information, please see Appendix 2

```

PORT      STATE SERVICE      VERSION
22/tcp    open  ssh          OpenSSH 4.4 (protocol 1.99)
80/tcp    open  http         Apache httpd 1.3.37 ((Unix) PHP/4.4.4)
139/tcp   open  netbios-ssn  Samba smbd 3.X - 4.X (workgroup: WORKGROUP)
445/tcp   open  netbios-ssn  Samba smbd 3.X - 4.X (workgroup: WORKGROUP)
3306/tcp   open  mysql        MySQL (unauthorized)
5903/tcp   open  vnc          VNC (protocol 3.7)
6000/tcp   open  X11          (access denied)
6003/tcp   open  X11          (access denied)
Device type: WAP|remote management|general purpose|broadband router|special
Running (JUST GUESSING): Gemtek embedded (96%), Siemens embedded (96%), AV
nux 2.6.X|2.4.X (95%), Aastra embedded (95%), Comtrend embedded (95%), AV
OS CPE: cpe:/h:gemtek:p360 cpe:/h:siemens:gigaset_se515dsl cpe:/o:avm:fritz
o:linux:linux_kernel:2.6.24 cpe:/h:comtrend:ct536 cpe:/h:avm:fritz%21box_f
Aggressive OS guesses: Gemtek P360 WAP or Siemens Gigaset SE515dsl wireless

```

Fig 2.3.1: nmap vulnerability scanning results

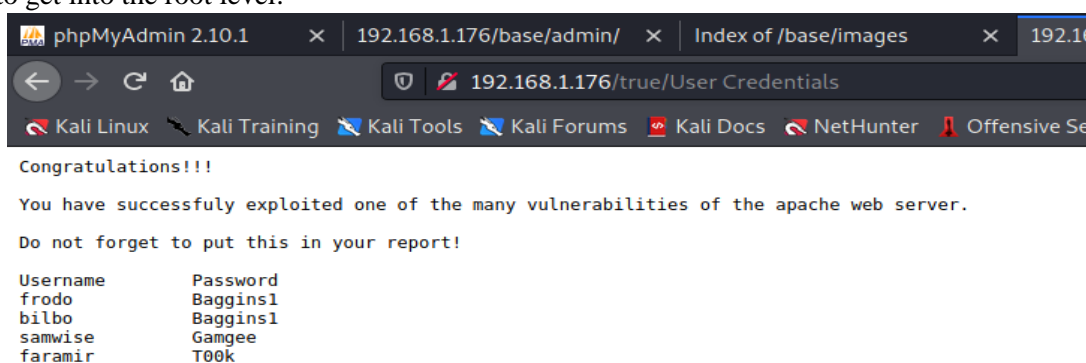

- Metasploit vulnerability result: using metasploit scanning, in fig 2.3.2 in the left hand side, the lists of open ports we found from nmap scanning, and then we put the open ports to the right

hand side terminal, in the metasploit scanner and the following results appeared. It helps us to detect quick idea of what attacks might be worth conducting.

The image shows two terminal windows. The left window is a Metasploit session where the user runs 'nmap -sV -p 80,22,110,25 192.168.1.176'. The output shows that ports 22, 80, 139, 445, and 3306 are open, with various services identified like OpenSSH, Apache, Samba, and MySQL. The right window shows the raw Nmap scan output for the same target, providing more detail on the open ports and services, including OS detection results.

Fig 2.3.2: Vulnerability scanning using metasploit

- **DIRB Vulnerability result:** with the useful tool dirb, we found out all the hidden directories that can be remotely accessible. The main threat arise after scanning with DIRB because with this scanning we found all credentials to get access into the directories that can lead an attacker also to get into the root level.

Also, at the end of the report, a detailed contrast in between OpenVas as well as Nessus has been given. Please see **Appendix A** for detail.

- **Zenmap Scanning:** by scanning the target IP address with nmap, we found the lists of open ports that are available to breach. Some of the open ports are ssh, http, mysql e.t.c (shown in fig. 2.3.1). To see more information, please see **Appendix D**

## 2.3 Vulnerability Exploitation

In this section, we are going to mention about the security holes that we have found so far. Also, we have provided the detail of attack in this section that can help an attacker to get into the root level of the system. Once the attacker get into the root level of the system, he eventually can change the credential data and steal valuable information that is kept on the system. It is crucial that the security should be designed in such way that no attacker can breach into the security hole, otherwise, this could be a threat.

- Root Privilege Escalation: with this technique, we were able to get access the root of the system. It is vulnerable as well because once an attacker get into the systems root, the attacker might able to manipulate information inside of it. Likewise, we did a basic malicious attack. When we entered into the system, after getting root access like the fig 2.3.1

```

Fig 2.3.4 Brute force attack using ncrack

### 3.0 Vulnerability Mitigation

Apart from the tools that we used for the vulnerability and exploitation. There are also more upgraded self-written tools that can be used for further attack. Vulnerabilities are massive factor that can wreak havoc in any business, of any size, at any time. However, if we look at the report in **Appendix B** of our OpenVAS report, we can see that the target has the highest level threat in tcp port 80, where Multiple Input Validation Vulnerabilities were found. Also, from the OpenVAS vulnerability detection result, we came to know that Successful exploitation could allow remote attackers to bypass security restrictions and to obtain a client's public host key during a connection attempt and use it to open and authenticate an SSH session to another server with the same access.

Apart from OpenVAS, from the report of Nessus scanner, we found that most of the vulnerable has a severity of multiple risks. The reason behind the vulnerability is that the versions that shows vulnerability, such versions may be affected by several issues, including buffer overflows, format string vulnerabilities, arbitrary code execution, 'safe mode' and clobbering of super-global. With such issues, an attacker could be able to overload the buffer that also exploit the attack to do some backdoor attacks, by which an attacker is able to steal some information that can be valuable. The detail has been provided in **Appendix C**.

Exploiting targets with privilege exploitation defines that the attacker can transfer files from any other machine or can be able to steal information from the victims machine as well. As we have done in our penetration test, when we done scanning with dirb scanning, we found the credentials and could easily get into the server, to avoid such problems, credentials should be encrypted in such manner even if the attacker get into the hidden directories the credentials could not be able to crack. This is how we can avoid the risk here.

Brute force attack using smart tools such as Hydra, ncrack, john can also be able to gather users credentials if the password pattern is likely to be common. Meanwhile in our testing, while we made brute force attack using these tools, some of vulnerabilities were found. It matches data with their string operation key search and hence made the server easy to exploit. This is a very common attack by the attacker. Very large companies are also affected by it. To avoid such issues, the most obvious way to prevent from brute-force attacks is to lock out accounts after a given number of wrong password attempts. (Esheridan, 2011)

There are some common risks associated with each of the given vulnerability and exploitation. The common factors are loss of financial situation, losses of user's personal data, losses of company's important documents and confidentiality, and damages of a company's reputation. There are many large companies where they had loss of million pounds and they were blamed at the same time by the users. This is how companies lose the trust of their people. To keep the basement strong, our team recommends you to put more strong security so that the system could be safe.

#### **4.0 Conclusion**

When conducting a large organisation, or any organisation that relies upon their online activities, it is highly recommended that the server and the system should be secured to avoid possible threats or risks that may come upon the company. Every year, millions of pounds have to pay to the attackers due to their successful post exploitation and they are selling users data to dark web or any other side. So this is very crucial to have more secured and layered security that cannot be breached.

#### **5.0 Overall Conclusion and Reflections**

The report has been made based on our learning outcomes from the module penetration testing. In this report, I have done scanning to the system in order to gather more information and let myself introduced with the target system. Secondly, by the process of determining vulnerabilities using few up to date tools I became more familiar with the possibilities of risks that are present into the target machine. And finally, after analysis possible risks and the security holes, I took some exploitation test and tried to breach into the system to cover the whole access in order to do malicious attack to make sure if I have the access to the root system to take control of it or not. Every of my tasks were successfully done except some technical issues that I faced during exploitation.

Finally, I have learned a lot of things during the entire experience. The most important things that I have learnt so far is, the process of analysing of different data, the ability of applying the best of my knowledge where I need to be. Also, this experience made me able to distinguish in between grey box and black box penetration testing. The most important thing that I need to mention is, I have covered different type of methodologies that need to be undertake before conducting a penetration test, also making of a good approach with a decision tree. I got introduced with many updated pen test tools that are very easy to use, and learnt some techniques to test a system which I believe will take me to the upper way during industrial experience.

## 7.0 Appendices

### Appendix A:

OpenVAS	Nessus
Open Source vulnerability tools	Not open source
Limited supportability	Has server side compatibility
Free for all	Paid version provides all the features
Calculates total vulnerabilities and results	Offers real time visibility
Common vulnerability coverage around 26000	Common vulnerability coverage around 47000

### Appendix B:

#### OpenVAS Report

## Scan Report

May 9, 2021

### Summary

This document reports on the results of an automatic security scan. All dates are displayed using the timezone "Coordinated Universal Time", which is abbreviated "UTC". The task was "ws1". The scan started at Sat May 8 23:34:34 2021 UTC and ended at Sat May 8 23:44:33 2021 UTC. The report first summarises the results found. Then, for each host, the report describes every issue found. Please consider the advice given in each description, in order to rectify the issue.

## Contents

1 Result Overview	2
2 Results per Host	2
2.1 192.168.1.176.....	2
2.1.1 High 80/tcp .....	2
2.1.2 High 22/tcp .....	3
2.1.3 High 55/tcp .....	4
2.1.4 Medium 80/tcp .....	5
2.1.5 Medium 22/tcp .....	9
2.1.6 Low 22/tcp .....	10

## 1 Result Overview

Host	High	Medium	Low	Log	False Positive
192.168.1.176	3	5	1	0	0
Total: 1	3	5	1	0	0

Vendor security updates are not trusted.

Overrides are off. Even when a result has an override, this report uses the actual threat of the result.

Information on overrides is included in the report.

Notes are included in the report.

This report might not show details of all issues that were found.

Issues with the threat level ☐Log☐ are not shown.

Issues with the threat level ☐Debug☐ are not shown.

Issues with the threat level ☐False Positive☐ are not shown.

Only results with a minimum QoD of 70 are shown.

This report contains all 9 results selected by the ☐Filtering described above. Before ☐Filtering there were 221 results.

## 2 Results per Host

2.1 192.168.1.176

Host scan start Sat May 8 23:35:00 2021 UTC

Host scan end Sat May 8 23:44:28 2021 UTC

Service (Port)	Threat Level
80/tcp	High
22/tcp	High
55/tcp	High
80/tcp	Medium
22/tcp	Medium
22/tcp	Low

2.1.1 High 80/tcp

h (CVSS: 7.5)
: Basic Analysis and Security Engine Multiple Input Validation Vulnerabilities
Summary
. . . continues on next page . . .

... continued from previous page ...
Basic Analysis and Security Engine (BASE) is prone to multiple input-validation vulnerabilities because it fails to adequately sanitize user-supplied input. These vulnerabilities include an SQL-injection issue, a cross-site scripting issue, and a local file-include issue.
<b>Vulnerability Detection Result</b> Installed version: 1.2.6 Fixed version: 1.4.4
<b>Impact</b> Exploiting these issues can allow an attacker to steal cookie-based authentication credentials, view and execute local files within the context of the webserver, compromise the application, access or modify data, or exploit latent vulnerabilities in the underlying database. Other attacks may also be possible.
<b>Solution:</b> Solution type: VendorFix Updates are available. Please see the references for details.
<b>Affected Software/OS</b> These issues affect versions prior to BASE 1.4.4.
<b>Vulnerability Detection Method</b> Details: Basic Analysis and Security Engine Multiple Input Validation Vulnerabilities OID:1.3.6.1.4.1.25623.1.0.100323
